The measurement result is a ratio of the channel power to the power in each offset. The results can be displayed as a ratio to the total power in each bandwidth, or as a ratio of the power spectral density. Simulated spectrum analyzer mode is for those who are accustomed to spectrum analyzers.

### Power statistics CCDF measurement

The complementary-cumulative distribution function (CCDF) traces provide you with how much time the waveform spends at or above a given power level. The percent of time the signal spends at or above the level defines the probability for that particular power level.

Minimum power at RF input	-40 dBm, average (nominal)

### Code domain measurement

The code domain measurement provides a tremendous amount of information about the in-channel characteristics of the W-CDMA signal. Code domain power (CDP) view directly informs the user of the active channels with their individual channel powers. The CDP view also leads you to symbol rate analysis such as symbol rate EVM and symbol power versus time.

*Power versus time measurement*

Power versus time measures the average power during the “useful part” of the EDGE or GSM burst and verifies that the power ramp is within the EDGE or GSM mask. The specified EDGE or GSM masks for both base transceiver stations and mobile stations are provided. Power versus time also lets you view the rise, fall, and “useful part” of the burst. The timings are referenced to the transmitter from bit 13 to 14 of the training sequence (midamble).

**Power vs. time and EDGE power vs. time**

*Output RF spectrum measurement*

The output RF spectrum measurements determine the spectral energy emitted into the adjacent channels. The measurements are divided into two types: spectrum due to  $3\pi/8$  8PSK or GMSK modulation and noise, and spectrum due to switching transients (burst ramping). A single offset can be examined with a corresponding trace, or up to 15 offsets can be measured with a tabular data display.
