## 1. General Description

The F81866A is the featured IO chip for Industrial PC system. Equipped with one IEEE 1284 parallel port, 6 UART ports with Multi drop function (9-bit protocol), SIR, ACPI management function and FDC. Each UART provides 16/32/64/128 bytes FIFO. The UART supports legacy speeds up to 115.2K bps as well as even higher baud rates of 230K, 460K, or 921K bps to support higher speed modems. The F81866A supports the enhanced parallel port (EPP) and the extended capabilities port (ECP). The F81866A supports keyboard and mouse interface which is 8042-based keyboard controller. The F81866A integrated with hardware monitor, 7 sets of voltage sensor, 3 sets of creative auto-controlling smart fans and 2 temperature sensor pins for the accurate dual current type temperature measurement for CPU thermal diode or external transistors 2N3906 and one local temperature.

The F81866A provides flexible features for multi-directional application. For instance, supports 72 GPIO pins, IRQ sharing function designed in UART feature for particular usage and accurate current mode H/W monitor will be worth in measurement of temperature. Others, the F81866A supports newest Intel PECI 3.0 interfaces for new generational CPU temperature usage, INTEL IBX PEAK, I2C and AMD TSI for temperature reading.

In order to save the current consumption when the system is in the soft off state which is so called power saving function. The power saving function supports the system boot-on not only by pressing the power button but also by the wake-up events via GPIO0x, GPIO1x, RI1#, and RI2#. When the system enters the S3/S4/S5 state, F81866A can cut off the VSB power rail which supplies power source to the devices like the LAN chip, the chipset, the SIO, the audio codec, DRAM, and etc. The PC system can be emulated to G3-like state when the system enters S3/S4/S5 states. At the G3-like state, the F81866A consumes 5VSB power rail only. The integrated two control pins are utilized to turn on or off VSB power rail in the G3-like status. The turned on VSB rail is supplied to a wake up device to fulfill a low power consumption system which supports a wake up function.

These features as above description will help you more and improve the product value. The F81866A is in the package of 128-LQFP. (14mm\*14mm)

### 6.2 FDC

The Floppy Disk Controller provides the interface between a host processor and one floppy disk drive. It integrates a controller and a digital data separator with write pre-compensation, data rate selection logic, microprocessor interface, and a set of registers. The FDC supports data transfer rates of 250 Kbps, 300 Kbps, 500 Kbps, 1 Mbps and 2 Mbps. It operates in PC/AT mode.

The FDC configuration is handled by software and a set of Configuration registers. Status, Data, and Control registers facilitate the interface between the host microprocessor and the disk drive, providing information about the condition and/or state of the FDC. These configuration registers can select the data rate, enable interrupts, drives, and DMA modes, and indicate errors in the data or operation of the FDC/FDD.

## 6.4 Hardware Monitor

### 6.4.1 General Description

#### 6.4.1.1 Voltage

For the 8-bit ADC has the 8mv LSB, the maximum input voltage of the analog pin is 2.048V. Therefore the voltage under 2.048V (ex:1.5V) can be directly connected to these analog inputs. The voltage higher than 2.048V should be reduced by a factor with external resistors so as to obtain the input range. Only 3Vcc is an exception for it is main power of the F81866A. Therefore 3Vcc can directly connect to this chip's power pin and need no external resistors. There are two functions in this pin with 3.3V. The first function is to supply internal analog power of the F81866A and the second function is that voltage with 3.3V is connected to internal serial resistors to monitor the +3.3V voltage. The internal serial resistors are two 150K $\Omega$ , so that the internal reduced voltage is half of +3.3V (See figure 6-1).

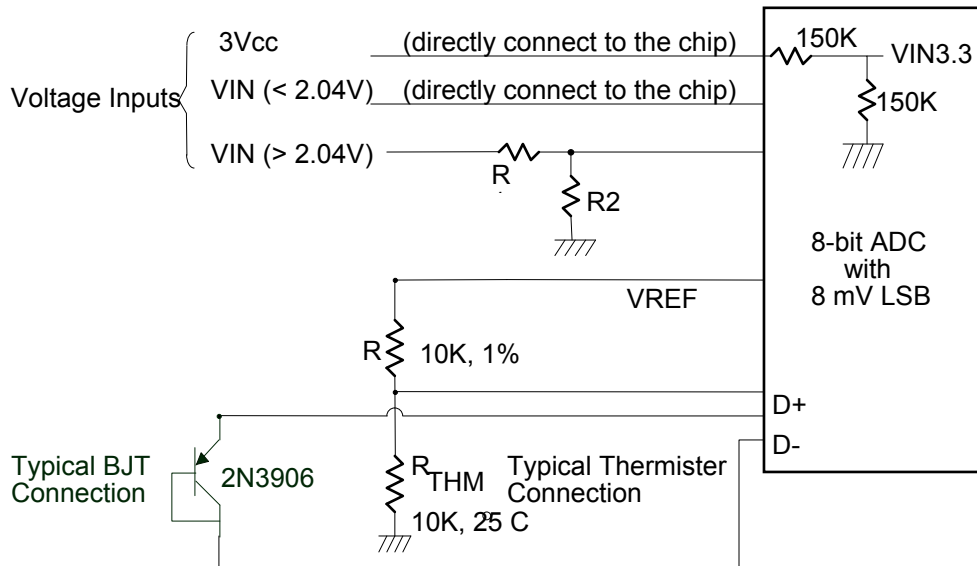

There are four voltage inputs in the F81866A and the voltage divided formula is shown as follows:

$$V_{IN} = V_{+12V} \times \frac{R_2}{R_1 + R_2}$$

where  $V_{+12V}$  is the analog input voltage, for example.

If we choose  $R_1=20K$ ,  $R_2=2K$ , the exact input voltage for  $V_{+12V}$  will be 1.09V, which is within the tolerance. As for application circuit, it can be refer to the figure shown as follows.

**Fig 6-1**

PME# interrupt for voltage is shown as figure 6-2. Voltage exceeding or going below high limit will cause an interrupt if the previous interrupt has been reset by writing "1" all the interrupt Status Register.

**Fig 6-2**

#### 6.4.1.2 Temperature Sensor

The F81866A monitors two remote temperature sensors. These sensors can be measured from  $-60^{\circ}\text{C}$  to  $127^{\circ}\text{C}$  for thermal diode & thermistor. More detail please refers to the register description.

##### Remote-sensor transistor manufacturers

Manufacturer	Model Number
Panasonic	2SB0709 2N3906
Philips	PMBT3906

**(1) Monitor Temperature from “thermistor”**

The F81866A can connect two thermistors to measure environment temperature or remote temperature. The specification of thermistor should be considered to (1)  $\beta$  value is 3435K (2) resistor value is  $10K\Omega$  at  $25^{\circ}C$ . In the Figure 6-1, the thermistor is connected by a serial resistor with  $10K\Omega$ , then connected to VREF.

**(2) Monitor Temperature from “thermal diode”**

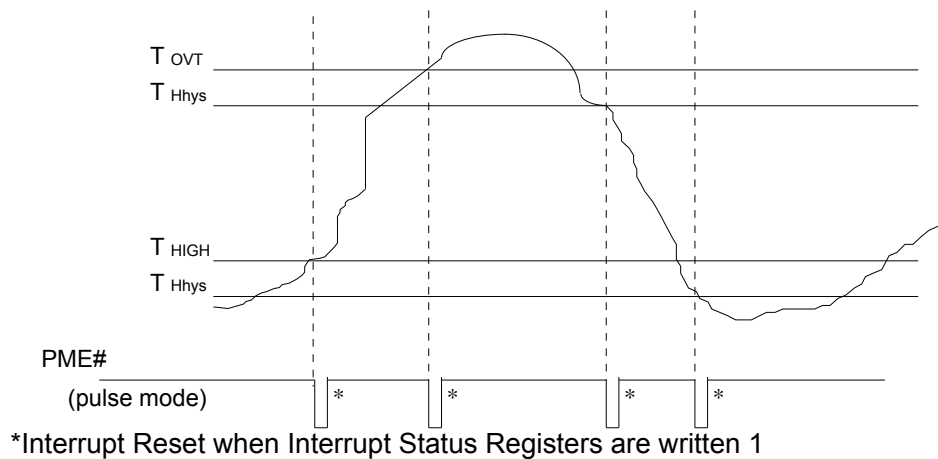

Also, if the CPU, GPU or external circuits provide thermal diode for temperature measurement, the F81866A is capable to these situations. The build-in reference table is for PNP 2N3906 transistor. In the Figure 6-1, the transistor is directly connected into temperature pins.

**Over Temperature Signal (OVT#)**

OVT# alert for temperature is shown as figure 6-3. When monitored temperature exceeds the over-temperature threshold value, OVT# will be asserted until the temperature goes below the hysteresis temperature.

**Fig 6-3**
**Temperature PME#**

PME# interrupt for temperature is shown as figure 6-4. Temperature exceeding high limit or going below hysteresis will cause an interrupt if the previous interrupt has been reset by writing “1” all the interrupt Status Register.

**Fig 6-4**

### 6.4.1.3 Fan

#### Fan speed count

Inputs are provided by the signals from fans equipped with tachometer outputs. The level of these signals should be set to TTL level, and maximum input voltage cannot be over 5V. If the input signals from the tachometer outputs are over the 5V, the external trimming circuit should be added to reduce the voltage to obtain the input specification.

Determine the fan counter according to:

$$\text{Count} = \frac{1.5 \times 10^6}{\text{RPM}}$$

In other words, the fan speed counter (12 bit resolution) has been read from register, the fan speed can be evaluated by the following equation.

$$\text{RPM} = \frac{1.5 \times 10^6}{\text{Count}}$$

As for fan, it would be best to use 2 pulses (4 phases fan) tachometer output per round. So the parameter "Count" under 5 bit filter is 4096~64 and RPM is 366~23438 based on the above equation. If using 8 phases fan, RPM would be from 183~11719.

#### Fan speed control

The F81866A provides 2 fan speed control methods:

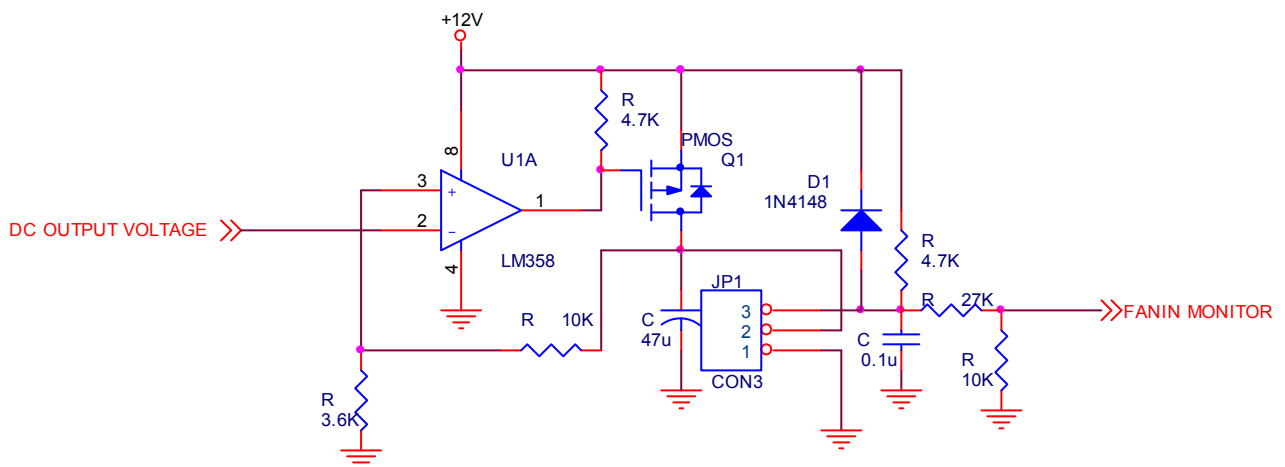

1. DAC FAN CONTROL
2. PWM DUTY CYCLE

**(1) DAC Fan Control**

The range of DC output is 0~VCC, controlled by 8-bit register. 1 LSB is about 0.013V (VCC=3.3V). The output DC voltage is amplified by external OP circuit, thus to reach maximum FAN OPERATION VOLTAGE, 12V. The output voltage will be given as followed:

$$\text{Output\_voltage (V)} = \text{VCC} \times \frac{\text{Programmed 8bit Register Value}}{256}$$

And the suggested application circuit for linear fan control would be:

**Fig 6-5**
**(2) PWM duty Fan Control**

The duty cycle of PWM can be programmed by a 8-bit register. The default duty cycle is set to 100%, that is, the default 8-bit registers is set to FFh. The expression of duty can be represented as follows.

$$\text{Duty\_cycle(\%)} = \frac{\text{Programmed 8bit Register Value}}{255} \times 100\%$$

**Fig 6-6**

**Fan speed control mechanism**

There are some modes to control fan speed and they are 1. Manual mode, 2. Auto mode (Stage & Linear). More detail, please refer to the description of registers & below figure.

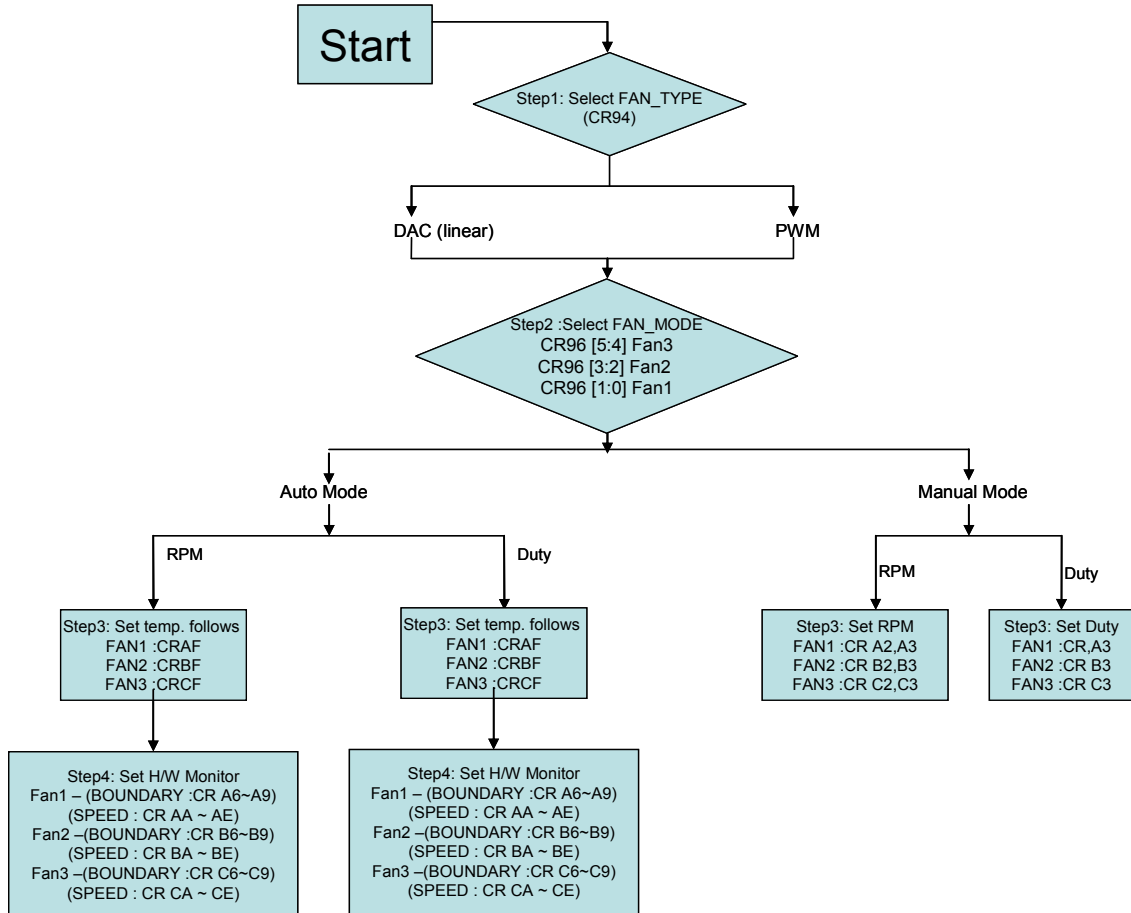

Fig 6-7 Fan type & mode selection flow

Each fan can be controlled by 8 kinds of temperature inputs: (1) T1 temperature (2) T2 temperature (3) T3 temperature (4) PECL temperature (5) 4 suits I2C master temperature.

### (1) Manual mode

For manual mode, it generally acts as the software fan speed control.

### (2) Auto mode

In auto mode, the F81866A provides the automatic fan speed control related to the temperature variation of CPU/GPU or the system. The F81866A can provide four temperature boundaries and five intervals, and each interval has its related fan speed count. All these values should be set by BIOS first. Take FAN1 for example, the 4 temperature boundaries could be set from the register 0xA6 to 0xA9 and the five intervals for fan speed control could be set from register 0xAA to 0xAE. The hysteresis setting (0 ~ 15°C) could also be found in the register 0x98.

There are two kinds for the auto modes they are the stage auto mode and the linear auto mode. The "FAN1\_INTERPOLATION\_EN" in the register 0xAFh is used for the linear auto mode enable.

The following examples explain the differences for the stage auto mode and linear auto mode.

### Stage auto mode

In this mode, the fan keeps in a same speed for each temperature interval. And there are two types of fan speed setting: PWM Duty and RPM %.

#### A. Stage auto mode (PWM Duty)

Set the temperature limits as 70°C, 60°C, 50°C, 40°C and the duty as 100%, 90%, 80%, 70%, 60%

Fig 6-8 Stage mode fan control illustration

- Once the temperature is under 40°C, the lowest fan speed keeps in the 60% PWM duty.
- Once the temperature is over 40°C, 50°C and 60°C, the fan speed will vary from 70%, 80% to 90% PWM duty and increasing with the temperature level.
- For the temperature higher than 70°C, the fan speed keeps in 100% PWM duty.
- If set the hysteresis is 3°C (default 4°C), once the temperature becomes lower than 67°C, the fan speed would reduce to 90% PWM duty.

#### B. Stage auto mode (RPM%)

Set the temperature as 70°C, 60°C, 50°C, 40°C and the corresponding fan speed is 6,000 RPM, 5,400 RPM, 4,800 RPM, 4,200 RPM, and 3,600 RPM (assume the Max Fan Speed is 6,000 RPM).

Fig 6-9 Stage mode fan control illustration

- a. Once the temperature is lower than 40°C, the lowest fan speed keeps in 3,600 RPM (60% of full speed).
- b. Once the temperature is higher than 40°C, 50°C and 60°C, the fan speed will vary from 4,200 RPM to 5,400 RPM and increasing with the temperature level.
- c. For the temperature higher than 70°C, the fan speed keeps in the full speed 6,000 RPM.
- d. If the hysteresis is set as 3°C (default 4°C), once temperature gets lower than 67°C, the fan speed would reduce to 5,400 RPM.

### Linear auto mode

Furthermore, F81866A also supports linear auto mode. The fan speed would increase or decrease linearly with the temperature. There are also PWM Duty and RPM% modes for it.

#### A. Linear auto mode (PWM Duty I)

Set the temperature as 70°C, 60°C, 50°C and 40°C and the duty is 100%, 80%, 70%, 60% and 50%.

Fig 6-10 Linear mode fan control illustration

- Once the temperature is lower than 40°C, the lowest fan speed keeps in the 50% PWM duty
- Once the temperature becomes higher than 40°C, 50°C and 60°C, the fan speed will vary from 50% to 80% PWM duty linearly with the temperature variation. The temp.-fan speed monitoring flash interval is 1sec.
- Once the temperature goes over 70°C, the fan speed will directly increase to 100% PWM duty (full speed).
- If set the hysteresis is 5°C (default is 4°C), once the temperature becomes lower than 65°C (instead of 70°C), the fan speed will reduce from 100% PWM duty and decrease linearly with the temperature.

### B. Linear auto mode (RPM%)

Set the temperature as 70°C, 60°C, 50°C, 40°C and the corresponding fan speed is 6,000 RPM, 4,800 RPM, 4,200 RPM, 3,600 RPM and 3,000 RPM (assume the Max Fan Speed is 6,000 RPM).

Fig 6-11 Linear mode fan control illustration

- Once the temperature is lower than 40°C, the lowest fan speed keeps in 3,000 RPM (50% of full speed).
- Once the temperature is over 40°C, 50°C and 60°C, the fan speed will vary from 3,000 to 4,800 RPM almost linearly with the temperature variation because the temp.-fan speed monitoring flash interval is 1sec.
- Once the temperature goes over 70°C, the fan speed will directly increase to full speed 6,000 RPM.
- If the hysteresis is 5°C (default is 4°C), once the temperature becomes lower than 65°C (instead of 70°C), the fan speed will reduce from full speed and decrease linearly with the temperature.

### PWMOUT Duty-cycle operating process

In both "Manual RPM" and "Temperature RPM" modes, the F81866A adjust PWMOUT duty-cycle according to current fan count and expected fan count. It will operate as follows:

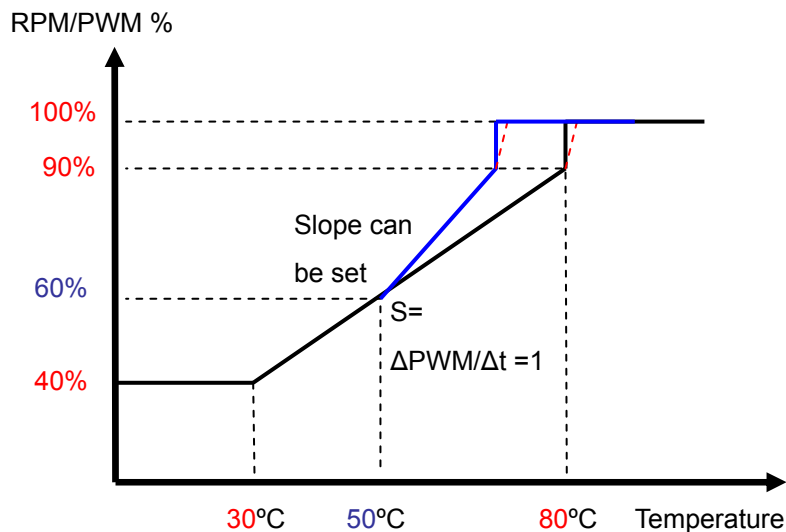

- When expected count is 0xFFFF, PWMOUT duty-cycle will be set to 0x00 to turn off fan.
- When expected count is 0x000, PWMOUT duty-cycle will be set to 0xFF to turn on fan with full speed.
- If both (1) and (2) are not true,  
When PWMOUT duty-cycle decrease to MIN\_DUTY(≠ 00h), obviously the duty-cycle will decrease to 00h next, the F81866A will keep duty-cycle at 00h for 1.6 seconds. After that,

the F81866A starts to compare current fan count and expected count in order to increase or decrease its duty-cycle. This ensures that if there is any glitch during the period, the F81866A will ignore it.

**Fig 6-12**

### Fan Speed Control with Multi-temperature

F81866A supports Multi-temperature for Fan 1 control. Fan 1 can be controlled up to 2 kinds of temperature inputs. This function works with linear auto mode which can extend to two linear slopes for Fan 1 control. As below graph shows, this machine can support more silence fan control in low temperature and high fan speed in the high temperature segment. More detail setting please refers to the related registers.

**Figure 6-13 Support 2 Linear Application with Multi-Temp. Setting**

In the figure below,  $T_{Fan1}$  is the scaled temperature for fan1.  $T_1$  is the real temperature for the fan1 sensor.  $T_a$  is another temperature data which can be used for linearly scale up or scale down the fan1 speed curve.  $T_b$  would be the point which starts the temperature scaling. The slope for the temperature curve over and under  $T_b$  would be  $C_{tup}$  and  $C_{tdn}$ .

1. C<sub>tup</sub>, C<sub>tdn</sub> Can be Programmed to 1, 1/2, 1/4, 0
2. Ta Can be Selected to the Same Temp. Source (Ex:T1)

$$TFan1 = T1 + (Ta - Tb) * C_{tup} ; TFan1 = T1 + (Ta - Tb) * C_{tdn}$$

Figure 6-14

In application, we can set the Ta as the 2<sup>nd</sup> sensor temperature and Tb as the temperature which starts the scaling. So if the 2<sup>nd</sup> sensor temperature Ta is higher or lower than Tb, the fan1 speed would be changed with it.

EX: Ta = T1, Tb = 60, C<sub>tu</sub> = 1, C<sub>td</sub> = 1/4

Figure 6-15

**FAN\_FAULT#**

Fan\_Fault# will be asserted when the fan speed doesn't meet the expected fan speed within a programmable period (default is 11 seconds) or when fan stops with respect to PWM duty-cycle which should be able to turn on the fan. There are two conditions may cause the FAN\_FAULT# event.

(1). When PWM\_Duty reaches 0xFF, the fan speed count can't reach the fan expected count on time. (Figure 6-16)

Fig 6-16

(2). After the period of detecting fan full speed, when PWM\_Duty > Min. Duty, and fan count is still in 0xFFFF.

## 6.5 Keyboard Controller

The KBC circuit provides the functions included a keyboard and/or a PS/2 mouse, and can be used with IBM-compatible personal computers or PS/2-based systems. The controller receives serial data from the keyboard or PS/2 mouse, checks the parity of the data, and presents the data to the system as a byte of data in its output buffer. The controller will assert an interrupt to the system when data are placed in its output buffer.

### Output Buffer

The output buffer is an 8-bit read-only register at I/O address 60h. The keyboard controller uses the output buffer to send the code received from the keyboard and data bytes required by

commands to the system.

### Input Buffer

The input buffer is an 8-bit write-only register at I/O address 60h or 64h. Writing to address 60h sets a flag to indicate a data write; writing to address 64h sets a flag to indicate a command write. Data written to I/O address 60h is sent to keyboard through the controller's input buffer only if the input buffer full bit in the status register is "0".

### Status Register

The status register is an 8-bit read-only register at I/O address 64h that holds information about the status of the keyboard controller and interface. It may be read at any time.

BIT	BIT FUNCTION	DESCRIPTION
0	Output Buffer Full	0: Output buffer empty 1: Output buffer full
1	Input Buffer Full	0: Input buffer empty 1: Input buffer full
2	System Flag	This bit may be set to 0 or 1 by writing to the system flag bit in the command byte of the keyboard controller (KCCB). It defaults to 0 after a power-on reset.
3	Command/Data	0: Data byte 1: Command byte
4	Inhibit Switch	0: Keyboard is inhibited 1: Keyboard is not inhibited
5	Mouse Output Buffer	0: Mouse output buffer empty 1: Mouse output buffer full
6	General Purpose Time-out	0: No time-out error 1: Time-out error
7	Parity Error	0: Odd parity 1: Even parity (error)

## 6.6 GPIO

F81866A has 72 pins GPIO in total. All GPIO supports digit IO for Input/Output control, Output data control, input status and High/Low Level/Pulse, Open Drain/Push Pull function selection. The GPIO0x and GPIO1x support interrupt status. The GPIO0x, GPIO1x, GPIO5x, and GPIO8x have different SIRQ channels. Please see 6.6.1 section for GPIO access methods and status:

### 6.6.1 GPIO Access Method

There are nine sets of GPIO in F81866A which can be accessed by three ways as below:

1. Configuration register port: Use 0x4E/0x4F (or 0x2E/0x2F) port with logic device number 0x06. Please refer to configuration register for detail.
2. Index/Data port: The index port is base address + 0 and data port is base address + 1. To access the GPIO register, user should first write index to index port and then read/write from/to data port. The index for each register is same as the definition in configuration register.
3. Digital I/O: This way could access GPIO data register only. It is used for quickly control the GPIO pins. The register for each address is as list:

**\*Available when GPIO\_DEC\_RANGE is set "1" (Configuration register index 0x27, bit 5)**

## 6.8 ACPI Function

The Advanced Configuration and Power Interface (ACPI) is a system for controlling the use of power in a computer. It lets computer manufacturer and user to determine the computer's power usage dynamically.

There are three ACPI states that are of primary concern to the system designer and they are designated S0, S3 and S5. S0 is a full-power state; the computer is being actively used in this state. The other two are called sleep states and reflect different power consumption when power-down. S3 is a state that the processor is powered down but the last procedural state is being stored in memory which is still active. S5 is a state that memory is off and the last procedural state of the processor has been stored to the hard disk. Take S3 and S5 as comparison, since memory is fast, the computer can quickly come back to the full-power state, the disk is slower than the memory and the computer takes longer time to come back to the full-power state. However, since the memory is off, S5 draws the minimal power comparing to S0 and S3.

ACPI includes three sub items as below:

1. Power Control (Include wake up via sleep state, wake up stage detection, AC loss & resume control methods)
2. Intel Power Saving Function (Deep Sleep Well, DSW: see next section for the detail)
3. EU Power Saving Function (EUP/ERP Command Lot 6.0: see next section for the detail)

Where item 2 & 3 could be coexisted via ERP\_CTRL0# (follow SLP\_SUS#) & ERP\_CTRL1# (After the system enters S3 1.024s & S5 6.4s, EUP/ERP mode could be achieved).

Before entering into the main section, let's check out the related hardware control signal first.

## 6.8.1 Power Control

### 6.8.1.1 Wake Up Via Sleep State

When the system is at the normal sleep state (S3, S4, S5) or deep sleep (G3') state, F81866A could wake up via PWSOUT# & PME#. See below for the related registers:

### 6.8.1.2 Wake Up Stage Detection

F81866A is counted on the chipset SLP\_S3#, SLP\_S4#/SLP\_S5# stage, to decide the wake up stage as below:

ACPI Stage	SLP_S3#	SLP_S4# /SLP_S5#
S0	H	H
S3	L	H
S5	L	L

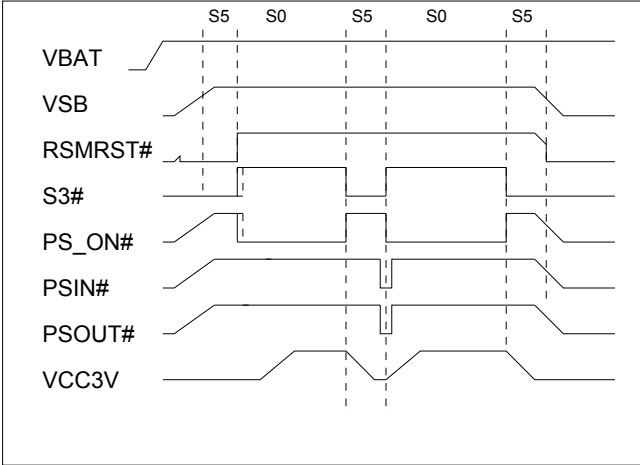

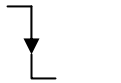

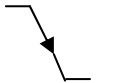

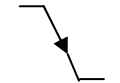

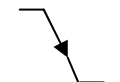

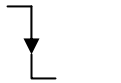

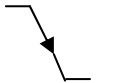

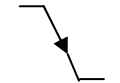

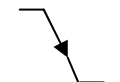

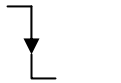

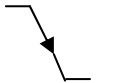

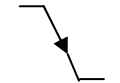

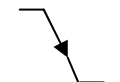

H: High; L: Low

Power saving mode would be activated via CR0A index E0 bit 7.

### 6.8.1.3 AC Loss & Resume Control Methods

There are 4 modes under power loss state via setting ACPI control register. The always on, always off, keep last state & bypass mode. In keep last state mode, one register will latch the status before power loss. If it is power on before power loss, it will automatically power on when power is resumed. If it is power off before power loss, it will remain power off when power is resumed. See below for the detail:

Mode	Explanation
Always on (S0)	When AC resume, the system will power on automatically (send a PWSOUT# low pulse and then sinking the PS_ON# low). See below for the timing: <div data-bbox="564 786 1203 1240" style="border: 1px solid black; padding: 10px; margin: 10px 0;"> </div>
Always off (S5)	When AC resume, the system is in off state and waiting for the wakeup events. See below for the timing: <div data-bbox="544 1368 1225 1906" style="border: 1px solid black; padding: 10px; margin: 10px 0;"> </div>
Bypass (follow the chipset after	When AC resume, inverting the S3 signal to PS_ON#. See below for the timing:

G3 stage)																
Keep last state	<p>ATXPG_IN, VCC (PWOK), VSB (RSMRST) and S3 signals to detect the sleep state while AC loss occur. One of the signal (ATXPG_IN or VCC under 2.8V or VSB under 2.8V) sinks low, SIO will latch the S3 signal to decide the system to be at “always on” or “always off” mode. See below table:</p> <table border="1" data-bbox="328 911 1436 1296"> <thead> <tr> <th>Signal AC loss state</th> <th>ATXPG</th> <th>VSB</th> <th>VCC</th> <th>AC resume</th> </tr> </thead> <tbody> <tr> <td>AC loss in S0/S1 (S3=1)</td> <td></td> <td></td> <td></td> <td>Always on</td> </tr> <tr> <td>AC loss in S3/S4/S5 (S3=0)</td> <td></td> <td></td> <td></td> <td>Always off</td> </tr> </tbody> </table>	Signal AC loss state	ATXPG	VSB	VCC	AC resume	AC loss in S0/S1 (S3=1)				Always on	AC loss in S3/S4/S5 (S3=0)				Always off

AC loss in S0/S1 (S3=1)				Always on												
AC loss in S3/S4/S5 (S3=0)				Always off												

### 6.8.2 Intel Power Saving Function Deep Sleep Well (DSW)

The F81866A supports Intel Cougar Point (CPT) Chipset timing for Sandy Bridge (Sugar Bay or Huron River Platform). There are 4 pins for CPT control: SUS\_WARN#, SUS\_ACK#, SLP\_SUS# and DPWROK.

For entering the Intel Deep Sleep Well (DSW) state, the PCH will assert SUS\_WARN# (low level) and turn off 5VDUAL. After the level of 5VDUAL is lower than 1.05V, F81866A will assert SUS\_ACK# to inform PCH it is ready for entering DSW. Finally, PCH will ramp down the internal VccSUS and assert SLP\_SUS# to F81866A. F81866A will turn off the 5VSB and 3VSB by ERP\_CTRL0# and enter the DSW state.

To exit DSW state, PCH will de-assert SLP\_SUS#, turn on the SUS rail FETs and ramp up internal 1.05V VccSUS. After the SUS rails voltages are up, RSMRST# will be deasserted and the PCH will release SUS\_WARN# so that the 5VDUAL will ramp up.

Because the DSW function is controlled by the F81866A instead of controlled by the PCH directly, there will be more wakeup events such as LAN, KB/Mouse, GPIO0x, GPIO1x, SIO RI# wake up rather than the 3 wakeup events (RTC, Power Button and GPIO27) for Intel DSW.

# F81866A

In order to achieve the lower power consumption, F81866A provides the ERP\_CTRL1# to turn off the V3A so that the system can enter the Fintek G3' state.

The block diagram below shows how the connection and control method for F81866A and PCH.

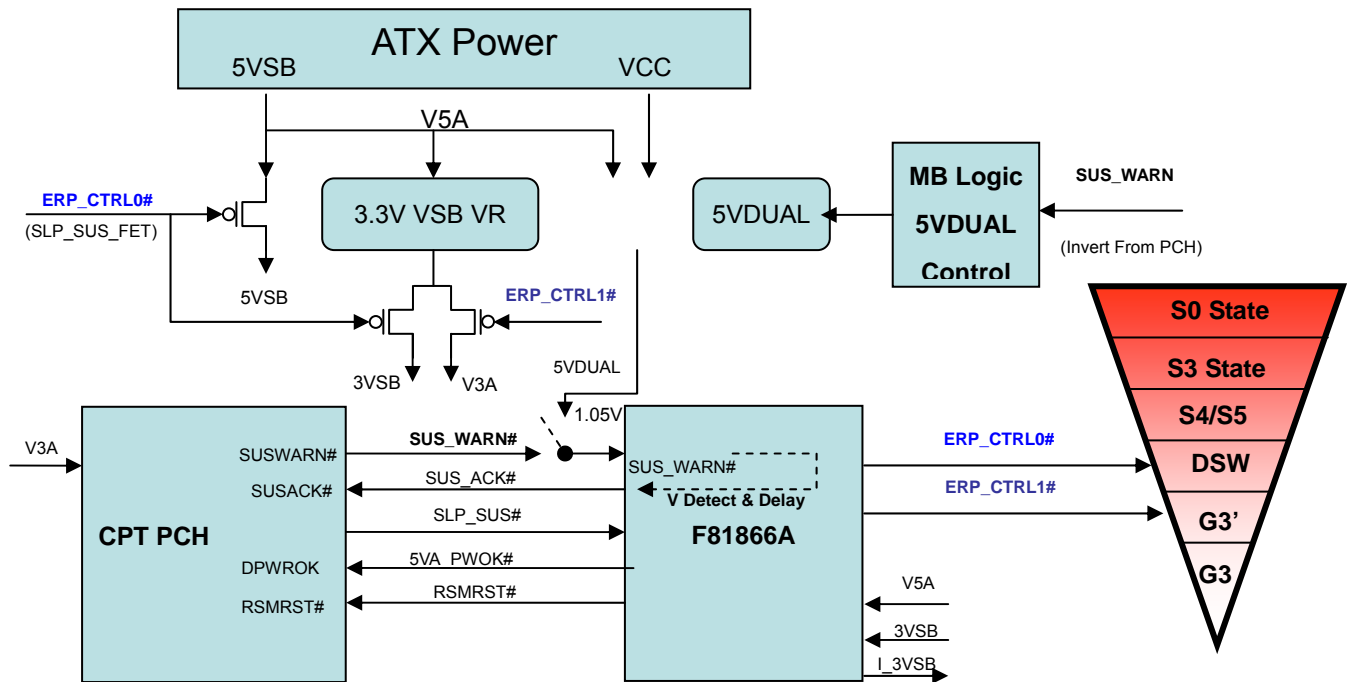

Fig 6-17

The register for setting this mode is at CR0A, index 0xEC [7:6]. When choose Intel DSW mode, ERP\_CTRL0#, & ERP\_CTRL1# would follow SLP\_SUS#. When choose Intel DSW + Fintek G3' mode, ERP\_CTRL0# would follows SLP\_SUS#, & ERP\_CTRL1# will enter Fintek ERP mode after entering DSW mode for 6.4s (default, the time is programmable).

In sum, there are three blocks in this mode (Please refer to the application circuit for the HW schematic):

- a. DSW Control Block:
  - a-1 SLP\_SUS#: SIO input pin from CPT PCH SLP\_SUS#.
  - a-2 SUS\_WARN#: SIO input pin from CPT PCH SUS\_WARN#.
  - a-3 SUS\_ACK#: SIO output pin to CPT PCH SUSACK#.
  - a-4 DPWROK: SIO output pin to CPT PCH DPWROK.
  
- b. ERP Control Block:
  - b-1 ERP\_CTRL0#: Support "CPT PCH DSW" control mode which is a low active signal to turn on/off 3VSB/5VSB power source by P MOSFET.
  - b-2 ERP\_CTRL1#: Support "Fintek G3'" control mode which is a low active signal to turn on/off 3VA/5VA power source by P MOSFET.

### 6.8.3 Power Saving Controller (Fintek ERP Mode)

The two pins, ERP\_CTRL0# and ERP\_CTRL1#, which control the standby power rail on/off to fulfill the purpose which decreases the power consumption when the system is in the sleep state or the soft-off state. These two pins connected to the external PMOSs and the defaults are high in the sleep state in order to cut off all the standby power rails to save the power consumption. If the system needs to support wake-up function, the two pins can be programmable to set which power rail to turn on. The programmable register is powered by the battery. So, the setting is kept even the AC power is lost when the register is set. At the power saving state (FINTeK calls it G3' state), the F81866A consumes 5VSB power rail only to realize a low power consumption system.

The register for setting this mode is at CR0A, index 0xEC [7:6]. When choose Fintek G3' mode, ERP\_CTRL0# & ERP\_CTRL1# will enter S5. After entering S5 for 6.4s (default, the time is programmable), these two pins would send high level signal and then cut off all the power sources except ATX\_5VSB (power consumption is about 15mW). In order to avoid the inrush current from ATX\_5VSB, F81866A also provide the soft start circuits at these two pins. See the related register for the soft start circuit (CR0A, index 0xEC [4]).

In sum, there are two blocks in this mode (Please refer to the application circuit for the HW schematic):

a. EUP Control Block:

ERP\_CTRL0# and ERP\_CTRL1# are low active signals to turn on/off 5VSB power source by P MOSFET.

b. Wake Up Event Block via:

Power Button	External LAN	PCH Internal LAN	PS2 KB/Mouse	SIO RI#	RTC	GPIO0x/1x
V	V	X	V	V	X	V

**Note:**

By pressing/triggering any of the above pin, the system could wake up from the sleep (S4/S5) DSW and G3' mode.

V: Supported.

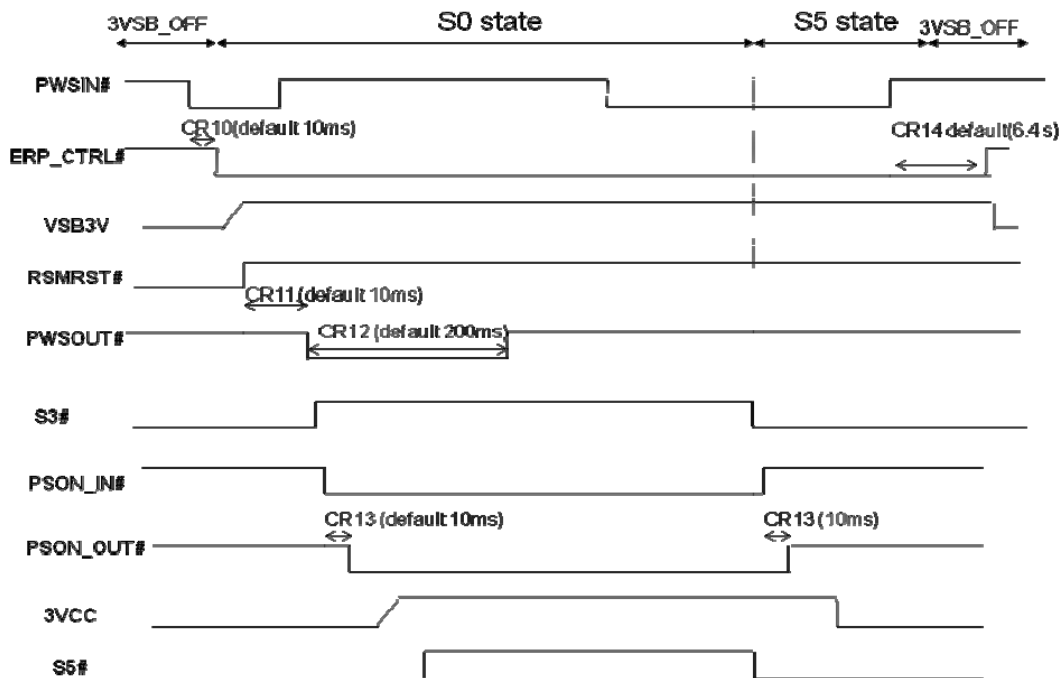

X: Does not supported.

## 6.9 UART

The F81866A provides up to 6 UART ports and supports IRQ sharing for system application. They are compatible with 16C550/16C650/16C750 and 16C850. The UARTs are used to convert data between parallel format and serial format. They convert parallel data into serial format on transmission and serial format into parallel data on receiver side. The serial format is formed by one start bit, followed by five to eight data bits, a parity bit if programmed and one ( 1.5 or 2 ) stop bits. The UARTs include complete modem control capability and an interrupt system that may be software trailed to the computing time required to handle the communication link. They have FIFO mode to reduce the number of interrupts presented to the host. Both receiver and transmitter have a 128-byte FIFO.

The UART control register control & define the asynchronous protocol data communications including data length, stop bit, parity & baud rate selection.

The below content is about the UARTs device register descriptions. All the registers are for software porting reference.

### 6.10 AMD TSI and Intel PECI 3.0 Functions

The F81866A provides Intel PECI/AMD TSI interfaces for new generational CPU temperature sensing. In AMD TSI interface, there are SIC and SID signals for temperature information reading from AMD CPU. The SIC signal is for clocking use, the other is for data transferring. More detail, please refer register description.

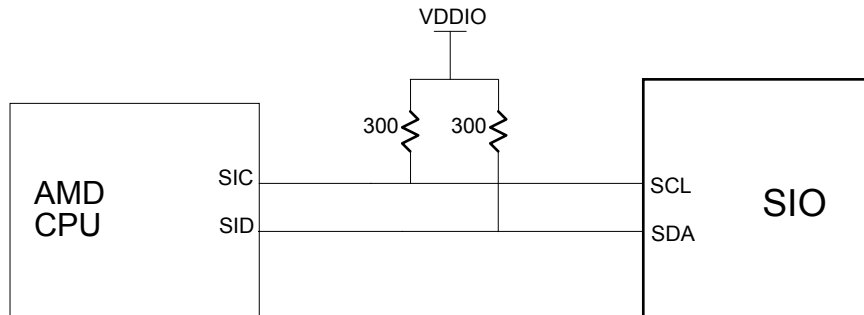

Fig 6-25 AMD TSI

In Intel PECI interface, the F81866A can connect to the CPU directly. The F81866A can read the temperature data from CPU, then the fan control machine of F81866A can implement the Fan to cool down the CPU temperature. The application circuit is as below.

Fig 6-26 Intel PECI

Please see below for the Intel PECI 3.0 Spec. commands. The F81866A integrated most of those commands for the future advantage application. More detail, please refer to the register descriptions.

## 6.11 Over Voltage Protection

F81866A over voltage protection function could protect the damage from voltage spikes via over voltage protection (OVP) function. Voltage protection function is enabled via setting the related register. When the force mode occurs, the system would shut down and then can not boot at all. Only re-plugging the power code (cut off VSB) could re-activate or re-boot the system at the force mode.

## 7. Register Description

The configuration register is used to control the behavior of the corresponding devices. To configure the register, using the index port to select the index and then writing data port to alter the parameters. The default index port and data port are 0x4E and 0x4F respectively. Pull down the RTS1# pin to change the default value to 0x2E/0x2F. To enable configuration, the entry key 0x87 must be written to the index port. To disable configuration, write exit key 0xAA to the index port. Following is an example to enable configuration and disable configuration by using debug.

- o 4e 87
- o 4e 87( enable configuration )
- o 4e aa( disable configuration )

The Following is a register map (total devices) grouped in hexadecimal address order, which shows a summary of all registers and their default value. Please refer to each device chapter if you want more detail information.

**Remark:**

GPIO also provides index/data port to access the whole GPIO registers. The index port is base address + 0 and data port is base address + 1. The index for each register is the same as the one for configuration register. For example, to write GPIO0 output enable register 0xAA, below is the procedure:

1. Write index port 0xF0.
2. Write data port 0xAA.
