

## TRANSITION-MODE PFC CONTROLLER

### 1 Features

- REALISED IN BCD TECHNOLOGY
- TRANSITION-MODE CONTROL OF PFC PRE-REGULATORS
- PROPRIETARY MULTIPLIER DESIGN FOR MINIMUM THD OF AC INPUT CURRENT
- VERY PRECISE ADJUSTABLE OUTPUT OVERVOLTAGE PROTECTION
- ULTRA-LOW ( $\leq 70\mu\text{A}$ ) START-UP CURRENT
- LOW ( $\leq 4\text{ mA}$ ) QUIESCENT CURRENT
- EXTENDED IC SUPPLY VOLTAGE RANGE
- ON-CHIP FILTER ON CURRENT SENSE
- DISABLE FUNCTION
- 1% (@  $T_j = 25^\circ\text{C}$ ) INTERNAL REFERENCE VOLTAGE
- -600/+800mA TOTEM POLE GATE DRIVER WITH UVLO PULL-DOWN AND VOLTAGE CLAMP
- DIP-8/SO-8 PACKAGES ECOPACK®

#### 1.1 APPLICATIONS

- PFC PRE-REGULATORS FOR:
  - IEC61000-3-2 COMPLIANT SMPS (TV,

- HI-END AC-DC ADAPTER/CHARGER
- ENTRY LEVEL SERVER & WEB SERVER

### 2 Description

The L6562 is a current-mode PFC controller operating in Transition Mode (TM). Pin-to-pin compatible with the predecessor L6561, it offers improved performance.

Figure 2. Block Diagram

## 2 Description (continued)

The highly linear multiplier includes a special circuit, able to reduce AC input current distortion, that allows wide-range-mains operation with an extremely low THD, even over a large load range.

The output voltage is controlled by means of a voltage-mode error amplifier and a precise (1% @  $T_j = 25^\circ\text{C}$ ) internal voltage reference.

The device features extremely low consumption ( $\leq 70\ \mu\text{A}$  before start-up and  $< 4\ \text{mA}$  running) and includes a disable function suitable for IC remote ON/OFF, which makes it easier to comply with energy saving norms (Blue Angel, EnergyStar, Energy2000, etc.).

An effective two-step OVP enables to safely handle overvoltages either occurring at start-up or resulting from load disconnection.

The totem-pole output stage, capable of 600 mA source and 800 mA sink current, is suitable for big MOS-FET or IGBT drive which, combined with the other features, makes the device an excellent low-cost solution for EN61000-3-2 compliant SMPS's up to 300W.

**Table 2. Absolute Maximum Ratings**

Symbol	Pin	Parameter	Value	Unit
$V_{CC}$	8	IC Supply voltage ( $I_{CC} = 20\ \text{mA}$ )	self-limited	V
---	1 to 4	Analog Inputs & Outputs	-0.3 to 8	V
$I_{ZCD}$	5	Zero Current Detector Max. Current	-50 (source) 10 (sink)	mA
$P_{tot}$		Power Dissipation @ $T_{amb} = 50^\circ\text{C}$ (DIP-8) (SO-8)	1 0.65	W
$T_j$		Junction Temperature Operating range	-40 to 150	$^\circ\text{C}$
$T_{stg}$		Storage Temperature	-55 to 150	$^\circ\text{C}$

Table 4. Pin Description

N°	Pin	Function
1	INV	Inverting input of the error amplifier. The information on the output voltage of the PFC pre-regulator is fed into the pin through a resistor divider.
2	COMP	Output of the error amplifier. A compensation network is placed between this pin and INV (pin #1) to achieve stability of the voltage control loop and ensure high power factor and low THD.
3	MULT	Main input to the multiplier. This pin is connected to the rectified mains voltage via a resistor divider and provides the sinusoidal reference to the current loop.
4	CS	Input to the PWM comparator. The current flowing in the MOSFET is sensed through a resistor, the resulting voltage is applied to this pin and compared with an internal sinusoidal-shaped reference, generated by the multiplier, to determine MOSFET's turn-off.
5	ZCD	Boost inductor's demagnetization sensing input for transition-mode operation. A negative-going edge triggers MOSFET's turn-on.
6	GND	Ground. Current return for both the signal part of the IC and the gate driver.
7	GD	Gate driver output. The totem pole output stage is able to drive power MOSFET's and IGBT's with a peak current of 600 mA source and 800 mA sink. The high-level voltage of this pin is clamped at about 12V to avoid excessive gate voltages in case the pin is supplied with a high V <sub>CC</sub> .
8	V <sub>CC</sub>	Supply Voltage of both the signal part of the IC and the gate driver. The supply voltage upper limit is extended to 22V min. to provide more headroom for supply voltage changes.

## 4 Application Information

### 4.1 Overvoltage protection

Under steady-state conditions, the voltage control loop keeps the output voltage  $V_o$  of a PFC pre-regulator close to its nominal value, set by the resistors  $R_1$  and  $R_2$  of the output divider. Neglecting ripple components, the current through  $R_1$ ,  $I_{R1}$ , equals that through  $R_2$ ,  $I_{R2}$ . Considering that the non-inverting input of the error amplifier is internally referenced at 2.5V, also the voltage at pin INV will be 2.5V, then:

$$I_{R2} = \frac{2.5}{R_2} = I_{R1} = \frac{V_o - 2.5}{R_1}.$$

If the output voltage experiences an abrupt change  $\Delta V_o > 0$  due to a load drop, the voltage at pin INV will be kept at 2.5V by the local feedback of the error amplifier, a network connected between pins INV and COMP that introduces a long time constant to achieve high PF (this is why  $\Delta V_o$  can be large). As a result, the current through  $R_2$  will remain equal to  $2.5/R_2$  but that through  $R_1$  will become:

$$I'_{R1} = \frac{V_o - 2.5 + \Delta V_o}{R_1}.$$

The difference current  $\Delta I_{R1} = I'_{R1} - I_{R2} = I'_{R1} - I_{R1} = \Delta V_o / R_1$  will flow through the compensation network and enter the error amplifier output (pin COMP). This current is monitored inside the L6562 and if it reaches about 37  $\mu A$  the output voltage of the multiplier is forced to decrease, thus smoothly reducing the energy delivered to the output. As the current exceeds 40  $\mu A$ , the OVP is triggered (Dynamic OVP): the gate-drive is forced low to switch off the external power transistor and the IC put in an idle state. This condition is maintained until the current falls below approximately 10  $\mu A$ , which re-enables the internal starter and allows switching to restart. The output  $\Delta V_o$  that is able to trigger the Dynamic OVP function is then:

$$\Delta V_o = R_1 \cdot 40 \cdot 10^{-6}.$$

An important advantage of this technique is that the OV level can be set independently of the regulated output voltage: the latter depends on the ratio of  $R_1$  to  $R_2$ , the former on the individual value of  $R_1$ . Another advantage is the precision: the tolerance of the detection current is 12%, that is 12% tolerance on  $\Delta V_o$ . Since  $\Delta V_o \ll V_o$ , the tolerance on the absolute value will be proportionally reduced.

Example:  $V_o = 400$  V,  $\Delta V_o = 40$  V. Then:  $R_1 = 40V / 40\mu A = 1M\Omega$ ;  $R_2 = 1M\Omega \cdot 2.5 / (400 - 2.5) = 6.289k\Omega$ . The tolerance on the OVP level due to the L6562 will be  $40 \cdot 0.12 = 4.8V$ , that is 1.2% of the regulated value.

When the load of a PFC pre-regulator is very low, the output voltage tends to stay steadily above the nominal value, which cannot be handled by the Dynamic OVP. If this occurs, however, the error amplifier output will saturate low; hence, when this is detected, the external power transistor is switched off and the IC put in an idle state (Static OVP). Normal operation is resumed as the error amplifier goes back into its linear region. As a result, the L6562 will work in burst-mode, with a repetition rate that can be very low.

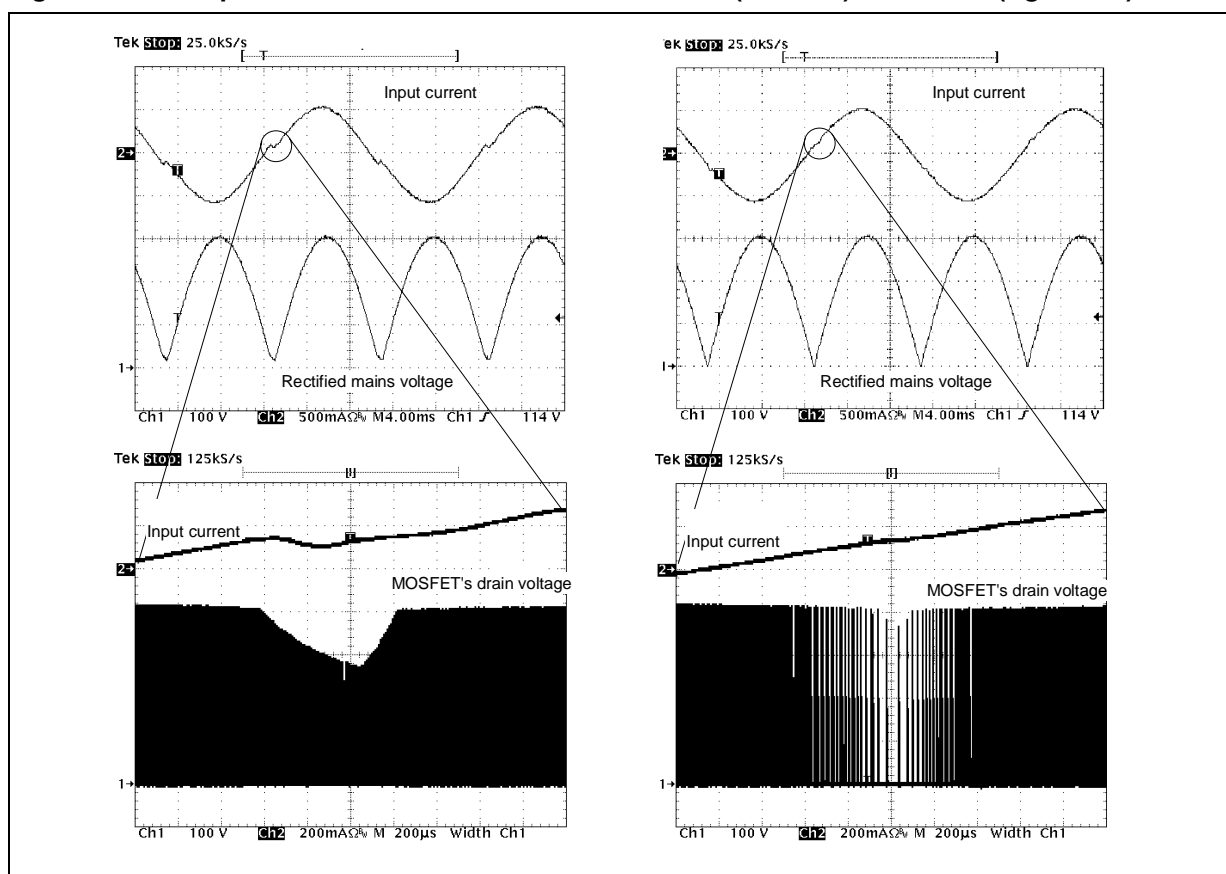

When either OVP is activated the quiescent consumption of the IC is reduced to minimize the discharge of the Vcc capacitor and increase the hold-up capability of the IC supply system.

## 4.2 THD optimizer circuit

The L6562 is equipped with a special circuit that reduces the conduction dead-angle occurring to the AC input current near the zero-crossings of the line voltage (crossover distortion). In this way the THD (Total Harmonic Distortion) of the current is considerably reduced.

A major cause of this distortion is the inability of the system to transfer energy effectively when the instantaneous line voltage is very low. This effect is magnified by the high-frequency filter capacitor placed after the bridge rectifier, which retains some residual voltage that causes the diodes of the bridge rectifier to be reverse-biased and the input current flow to temporarily stop.

**Figure 22. THD optimization: standard TM PFC controller (left side) and L6562 (right side)**

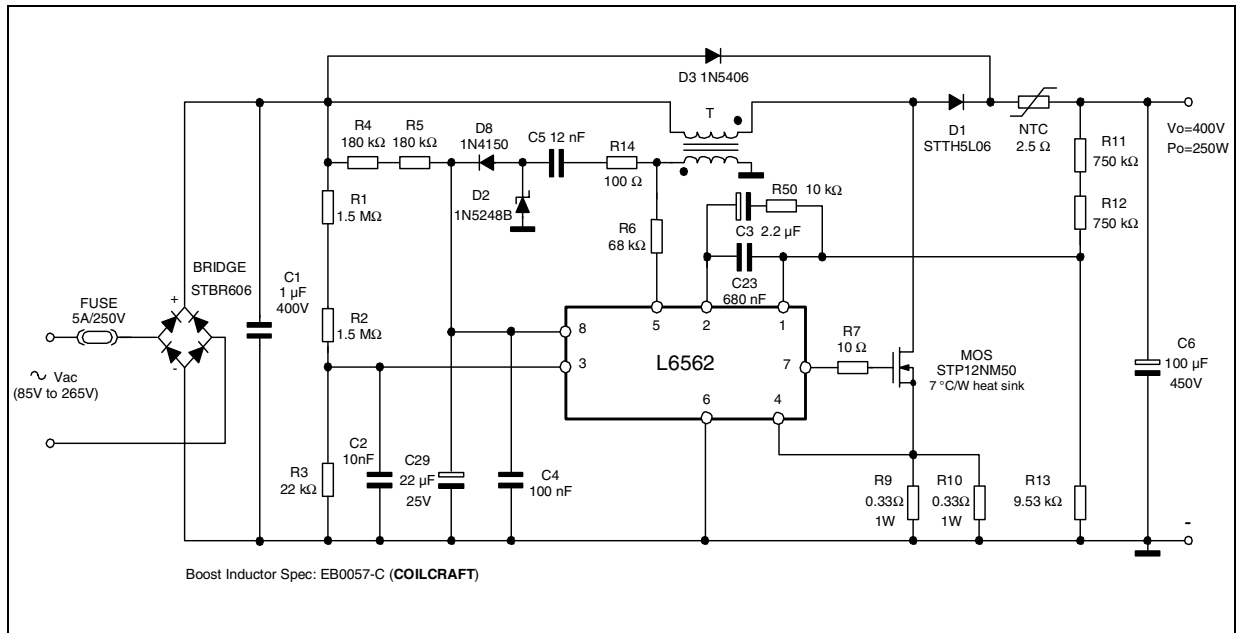

To overcome this issue the circuit embedded in the L6562 forces the PFC pre-regulator to process more energy near the line voltage zero-crossings as compared to that commanded by the control loop. This will result in both minimizing the time interval where energy transfer is lacking and fully discharging the high-frequency filter capacitor after the bridge. The effect of the circuit is shown in figure 23, where the key waveforms of a standard TM PFC controller are compared to those of the L6562.

Essentially, the circuit artificially increases the ON-time of the power switch with a positive offset added to

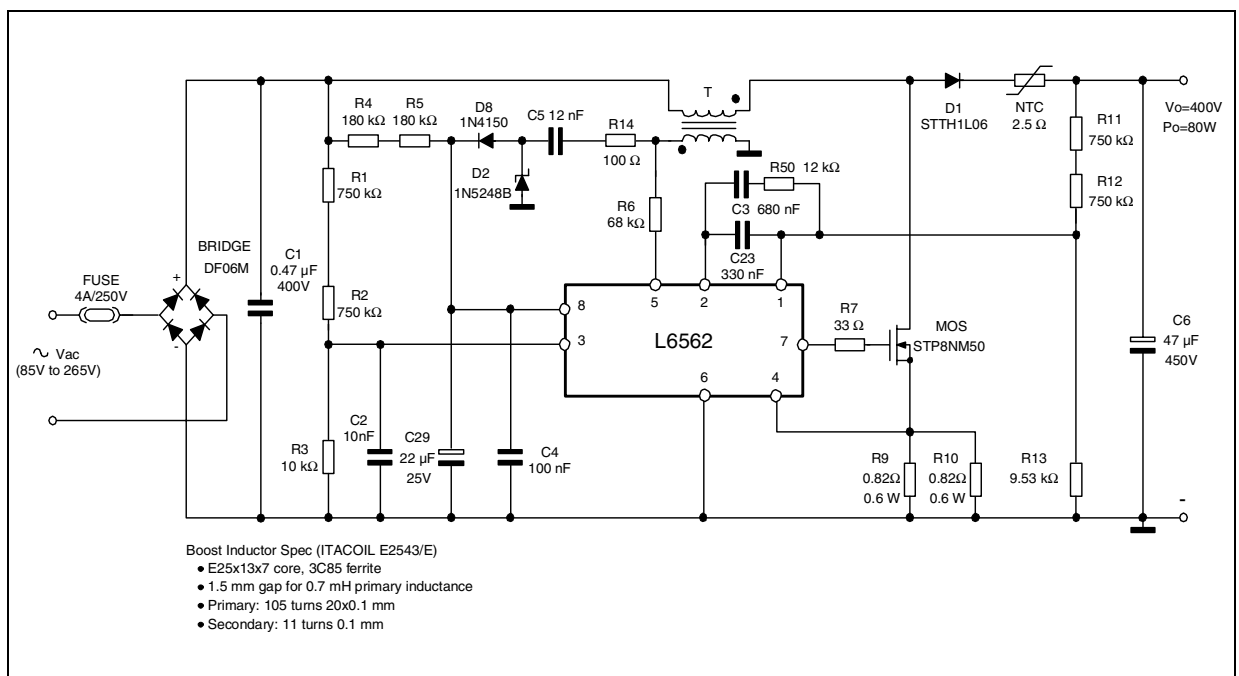

the output of the multiplier in the proximity of the line voltage zero-crossings. This offset is reduced as the instantaneous line voltage increases, so that it becomes negligible as the line voltage moves toward the top of the sinusoid.

To maximally benefit from the THD optimizer circuit, the high-frequency filter capacitor after the bridge rectifier should be minimized, compatibly with EMI filtering needs. A large capacitance, in fact, introduces a conduction dead-angle of the AC input current in itself - even with an ideal energy transfer by the PFC pre-regulator - thus making the action of the optimizer circuit little effective.

## 5 Package Information

In order to meet environmental requirements, ST offers these devices in ECOPACK<sup>®</sup> packages. These packages have a Lead-free second level interconnect. The category of second Level Interconnect is marked on the package and on the inner box label, in compliance with JEDEC Standard JESD97. The maximum ratings related to soldering conditions are also marked on the inner box label. ECOPACK is an ST trademark.

ECOPACK specifications are available at: [www.st.com](http://www.st.com).
