Description

The CPC1560 is a 1-Form-A (Single Pole, Normally Open) optically isolated MOSFET switch that provides fast turn-on of loads up to 600mA$_{DC}$ in a DC-Only configuration, 300mA$_{rms}$ in an AC/DC configuration; active current-limit circuitry; and 3750V$_{rms}$ of I/O isolation.

Fast turn-on is accomplished with the use of an external charge storage capacitor that provides the necessary charge required by the internal switching MOSFETs. The device charges this capacitor, through bootstrap diodes, from the load voltage, thereby alleviating the need for an additional power supply.
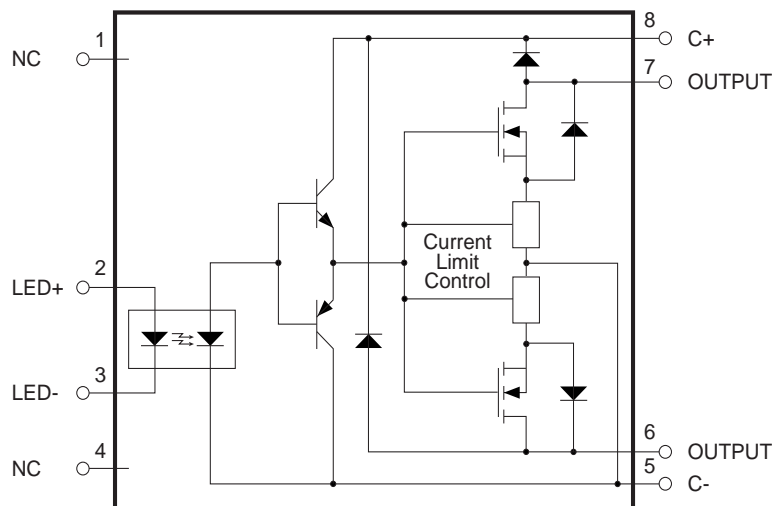

The CPC1560 incorporates thermal shutdown circuitry for improved survivability in harsh environments, and is designed to pass regulatory voltage surge requirements when provided with appropriate over-voltage protection circuitry.

Designed specifically for environmentally demanding AC or DC applications, where printed circuit board space is at a premium and additional power supplies are not available, the CPC1560 is an ideal solution.

2. Introduction

The CPC1560 is an optically coupled Solid State Relay (SSR) that is self-biased from the load supply. An external charge storage capacitor is used to greatly speed up SSR turn-on. The CPC1560 also incorporates current limiting and a thermal shutdown feature in the output circuitry, which make the device ideal for use in harsh conditions.

3. Functional Description

Internally, the device is composed of an LED, a photovoltaic array with control circuitry, and two MOSFET output switches.

Input current to the LED is the turn-on signal to the SSR's output MOSFET switches. The LED illuminates the photovoltaics, which provide current to the gates of the output MOSFETs, causing them to conduct. The charge provided to the MOSFET gates initially includes the charge stored in the external capacitor, which causes the SSR to conduct much more quickly than if only the photovoltaic current were used.

When the Load Voltage (V_L) is first applied to the inactive outputs, the external storage capacitor begins to charge. To ensure proper operation, the storage capacitor should be equal to or greater than the total gate capacitance of the two output MOSFET switches. The charge is passed through bootstrap diodes, which prevent the charge from escaping and discharging the capacitor through the MOSFET output switch when the SSR is turned on. The input control current is applied, then the charge is transferred from the storage capacitor through the internal NPN bipolar transistor along with the charge from the photovoltaic, to the MOSFET gates to accomplish a rapid turn-on. After the capacitor has discharged and the MOSFETs have turned on, the photocurrent from the photovoltaic continues to flow into the gates, keeping the MOSFETs turned on.

When the input control current is removed, the gate current stops flowing and the PNP bipolar transistor is on, discharging the MOSFET gates. The MOSFETs are now off. At this point the capacitor begins to recharge for the next turn on cycle.

The non-conducting, optical coupling space between the LED and the photovoltaics provides 3750V_{rms} of isolation between the control input and the switched output of the CPC1560.

Important things to note about the operation of the CPC1560:
- The device is designed to maintain its guaranteed operating characteristics with DC input control current (I_F) in the range of 2.5mA to 10mA (see). The device will operate at input currents above and below this range, but device operating characteristics are not guaranteed.
- There is a minimum LED input current required for the device to shut off: typically about 0.43mA at 25°C (see).
- The output switch will only withstand a maximum of 60 volts across its terminals before breaking down (see). The maximum voltage generally occurs when the load is off.

The CPC1560 has two different operating configurations: unidirectional DC-only configuration, and bidirectional AC/DC configuration.

In the unidirectional DC-only configuration, the device switches load voltages with a fixed polarity, while in the AC/DC configuration it can switch voltages with either positive or negative polarities.

The advantage of operating the device in the DC-only configuration is the ability to switch larger load currents. The advantage of operating it in the AC/DC configuration is the flexibility of switching load voltages of either polarity.

4. Device Configuration

4.1 LED Resistor

To assure proper operation of the CPC1560, the LED resistor selection should comply with the recommended operating conditions. Although the LED is capable of being operated up to the absolute maximum ratings, this is not recommended. Operating the LED beyond the recommended operating conditions may prevent the current limit and thermal shutdown functions from performing properly. The equation used to calculate the max resistor value:

$$R_{LED\_MAX} = \frac{V_{IN\_MIN} - V_{LOW\_MAX} - V_{F\_MAX}}{I_{F\_MIN}}$$
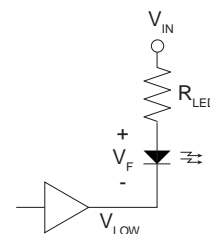

- I_{F_MIN} = Minimum Input Control Current
- V_{IN_MIN} = Minimum Input Power Source
- V_{LOW_MAX} = Maximum Logic Level Low Voltage
- V_{F_MAX} = Maximum Forward Voltage Drop of LED
- R_{LED_MAX} = Maximum Input Resistor to LED

PRELIMINARY

(C$_{LOAD}$) and load Inductance (L$_{LOAD}$), along with other recommended operating conditions given in this datasheet, are constrained by the 85°C operation of most industrial applications. For lower operating temperature ranges, these values can be de-rated using the information provided in the temperature graphs in this datasheet.

5.2.1 Effects of Ambient Temperature

One of the most important factors is the temperature variation of the environment. From the **Maximum Allowed Energy Dissipation During t$_{RISE}$** graphs (AC and DC) in this datasheet, the user can see how the energy dissipated in the part during t$_{RISE}$ increases with increasing ambient temperature.

The operating frequency of the device is directly related to the amount of energy dissipated in it during the transition times, t$_{RISE}$ and t$_{FALL}$, which increases rapidly with temperature, as seen in the previously mentioned graphs. Depending on the operating temperature range of the application, the user must derate the maximum allowed energy in the part during t$_{RISE}$ and t$_{FALL}$ (according to the temperature graphs provided) in order to limit the operating switching frequency.

5.3 Current Limit and Thermal Shutdown

5.3.1 Current Limit

The CPC1560 has a current limit feature in which current through the output switches is limited to a value larger than the recommended operating current.

In the AC/DC configuration, the CPC1560 has bidirectional current limiting, which consists of current limit circuits in both positive and negative polarities. In the DC-only configuration, the DC current limit consists of the parallel of the two AC current limit circuits in the positive DC polarity.

The current limit function has a negative temperature coefficient in which increasing temperature lowers the current limit threshold of the device. Prolonged periods of current limiting will cause the temperature of the device to increase, and, if allowed to continue, will activate the device's thermal shutdown circuitry, forcing the output switches to turn off.

5.3.2 Thermal Shutdown

The purpose of the thermal shutdown feature is to completely shut down the operation of the device when its junction temperature has gone above 130°C, whether this is due to high power dissipation in the device in the form of heat or an increase in the ambient temperature.

The thermal shutdown feature and the current limit feature provide great power cross immunity to the device for improved survivability in harsh environments.

5.4 dV/dt Fault Tolerance

The CPC1560 device has a finite dV/dt fault tolerance for both the AC/DC and DC-only configurations, which must not be exceeded.

The dV/dt tolerance for the device in the AC/DC configuration is double that of the DC-only configuration (see **"Absolute Maximum Ratings" on page 3**). This is because the dV/dt value of the CPC1560 is inversely proportional to the size of the output switch's C$_{rss}$, or "reverse transfer capacitance," and this capacitance in the DC-only configuration is double that in the AC/DC configuration.

5.5 Power Derating

Bear in mind the power rating of the CPC1560 when operating the device at elevated temperatures. The Absolute Maximum Ratings table shows that the maximum allowed power dissipation at 25°C is 800mW, which is the maximum power that can be dissipated before the junction temperature of the device reaches 125°C.

In order to keep the CPC1560 operating within its power rating, use the Maximum Allowed Load Current graphs provided earlier in this document.

5.6 Rise and Fall Times

The CPC1560 has rise and fall times that are primarily limited by internal parasitic elements of the device; the load components only play a secondary role. This can be appreciated in the turn-off graph of an application circuit operating at 45V, where the slope of the load voltage starts scooping down into a more capacitive shape after approximately 15 volts.

(Supply=45V$_{DC}$, R$_{LOAD}$ =75Ω)
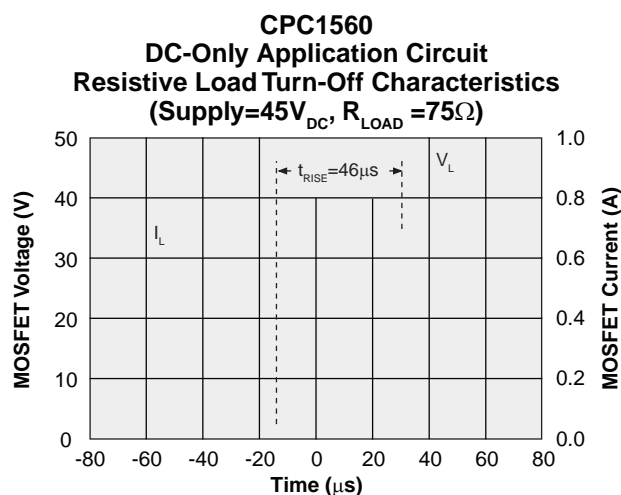

5.7 Over-Voltage Protection

5.7.1 Stored Energy in the Load

During the CPC1560's switching periods, energy is transferred between the load components, the CPC1560 device, and, if used, the over-voltage protection circuitry.

When the output switch turns off, inductive loads (L$_{LOAD}$) transfer their stored energy into the MOSFET switches, the load capacitance, and the over-voltage protector. (See the turn-off graph for a 45V inductive load application circuit.)

When the output switch turns on, the energy in the load inductor is zero, and the load capacitor (C$_{LOAD}$) must transfer its stored energy into the MOSFET.

5.7.2 Protection Methods

One way to protect the CPC1560 and application circuit components from damage when excessive stored energy is suddenly released into the output MOSFETs of the CPC1560, is to add a Transient Voltage Suppressor (TVS) across the output switches. Use a unidirectional TVS from the outputs to C- for the DC-only configuration, and use a bidirectional TVS across the output pins for the AC/DC configuration as shown in the diagrams below.

In order to calculate the required TVS value, the user has to compare working voltage of the application circuit to the breakdown voltage of the CPC1560 with the TVS maximum clamping voltage ratings. The TVS maximum clamping voltage capability must be, at a minimum, equal to the specific peak pulse current of the load. This must be done to ensure the TVS can easily absorb any excess energy coming from the inductive load (L_{LOAD}).

In addition to the TVS, other protection techniques are also available depending on the type of load the user is trying to switch. For purely resistive loads the user may rely on the output transistor to handle any parasitic energy. For very low to moderately inductive loads (*e.g.* remote switching of a load through a long cable), a voltage suppressor or TVS can be used as explained before. For heavily inductive loads, a fly-back diode connected across the load element is recommended

For much higher inductive loads, other circuit techniques, device ratings and/or protector types must be considered[1]. Of paramount importance is that the designer know the characteristics of the load being switched.

6. Manufacturing Information

6.1 Soldering

For proper assembly, the component must be processed in accordance with the current revision of IPC/JEDEC standard J-STD-020. Failure to follow the recommended guidelines may cause permanent damage to the device resulting in impaired performance and/or a reduced lifetime expectancy.
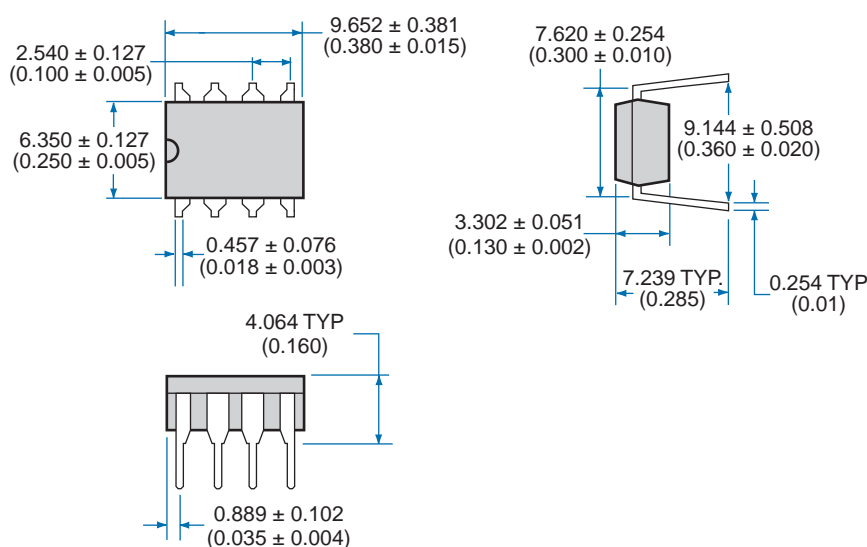

6.2 Washing

Clare does not recommend ultrasonic cleaning or the use of chlorinated hydrocarbons.
