Current-Limiting Power Distribution Switches

General Description

The MIC2095/97/98/99 family of switches are self-contained, current-limiting, high-side power switches, ideal for power-control applications. These switches are useful for general purpose power distribution applications such as digital televisions (DTV), printers, set-top boxes (STB), PCs, PDAs, and other peripheral devices.

The current limiting switches feature either a fixed 0.5A/0.9A or resistor programmable output current limit. The family also has fault blanking to eliminate false noise-induced, over current conditions. After an over-current condition, these devices automatically restart if the enable pin remains active. The MIC2097 switch offers a unique new patented Kickstart feature, which allows momentary high-current surges up to the secondary current limit (I_{LIMIT_2nd}). This is useful for charging loads with high inrush currents, such as capacitors.

The MIC2095/97/98/99 family of switches provides under-voltage, over-temperature shutdown, and output fault status reporting. The family also provides either an active low or active high, logic level enable pin.

The MIC2095/97/98/99 family is offered in a space saving 1.6mm x 1.6mm Thin MLF[®] (TMLF) package.

Datasheets and support documentation can be found on Micrel's web site at: www.micrel.com.

Features

- MIC2095: 0.5A fixed current limit
- MIC2098: 0.9A fixed current limit
- MIC2097/99: Resistor programmable current limit – 0.1A to 1.1A
- MIC2097: Kickstart for high peak current loads
- Under voltage lock-out (UVLO)
- Soft start prevents large current inrush
- Automatic-on output after fault
- Thermal protection
- Enable active high or active low
- 170m Ω typical on-resistance @ 5V
- 2.5V – 5.5V operating range

Applications

- Digital televisions (DTV)
- Set top boxes
- PDAs
- Printers
- USB / IEEE 1394 power distribution
- Desktop and laptop PCs
- Game consoles
- USB keyboard
- Docking stations

Functional Description and Application Information

V_{IN} and V_{OUT}

V_{IN} is both the power supply connection for the internal circuitry driving the switch and the input (Source connection) of the power MOSFET switch. V_{OUT} is the Drain connection of the power MOSFET and supplies power to the load. In a typical circuit, current flows from V_{IN} to V_{OUT} toward the load. Since the switch is bi-directional when enabled, if V_{OUT} is greater than V_{IN} , current will flow from V_{OUT} to V_{IN} .

When the switch is disabled, current will not flow to the load, except for a small unavoidable leakage current of a few micro amps. However, should V_{OUT} exceed V_{IN} by more than a diode drop (~0.6V), while the switch is disabled, current will flow from output to input via the power MOSFET's body diode. When the switch is enabled, current can flow both ways, from V_{IN} to V_{OUT} , or V_{OUT} to V_{IN} .

C_{IN}

A minimum 1 μ F bypass capacitor positioned as close as possible to the V_{IN} and GND pins of the switch is both good design practice and required for proper operation of the switch. This will control supply transients and ringing. Without a sufficient bypass capacitor, large current surges or a short may cause sufficient ringing on V_{IN} (from supply lead inductance) to cause erratic operation of the switch's control circuitry. For best performance a good quality, low-ESR ceramic capacitor is recommended.

An additional 22 μ F (or greater) capacitor, positioned close to the V_{IN} and GND pins of the switch is necessary if the distance between a larger bulk capacitor and the switch is greater than 3 inches. This additional capacitor limits input voltage transients at the switch caused by fast changing input currents that occur during a fault condition, such as current limit and thermal shutdown.

When bypassing with capacitors of 10 μ F and up, it is good practice to place a smaller value capacitor in parallel with the larger to handle the high frequency components of any line transients. Values in the range of 0.1 μ F to 1 μ F are recommended. Again, good quality, low-ESR capacitors, preferably ceramic, should be chosen.

C_{OUT}

An output capacitor is recommended to reduce ringing and voltage sag on the output during a transient condition. A value between 1 μ F and 10 μ F is recommended, however, larger values can be used.

Limitations on C_{OUT}

The part may enter current limit when turning on with a large output capacitance. This is an acceptable condition, however, if the part remains in current limit for a time greater than t_{D_FAULT} , the FAULT pin will assert low. The maximum value of C_{OUT} may be approximated by the following equation:

$$C_{OUT_MAX} = \frac{I_{LIMIT_MIN} \times t_{D_FAULT_MIN}}{V_{IN_MAX}} \quad \text{Eq. 1}$$

Where: I_{LIMIT_MIN} and $t_{D_FAULT_MIN}$ are the minimum specified values listed in the Electrical Characteristic table and V_{IN_MAX} is the maximum input voltage to the switch.

Current Sensing and Limiting

The current limiting switches protect the system power supply and load from damage by continuously monitoring current through the on-chip power MOSFET. Load current is monitored by means of a current mirror in parallel with the power MOSFET switch. Current limiting is invoked when the load exceeds the over-current threshold. When current limiting is activated the output current is constrained to the limit value, and remains at this level until either the load/fault is removed, the load's current requirement drops below the limiting value, or the switch goes into thermal shutdown.

Kickstart™

The MIC2097 has a Kickstart feature that allows higher momentary current surges before the onset of current limiting. This permits dynamic loads, such as small disk drives or portable printers to draw the inrush current needed to overcome inertial loads without sacrificing system safety. The Kickstart parts differ from the non-Kickstart parts which more rapidly limit load current, potentially starving a motor and causing the appliance to stall or stutter.

During the Kickstart delay period, (typically 105ms), a secondary current limit (nominally set at 1.5A), is in effect. If the load demands a current in excess the secondary limit, Kickstart parts act immediately to restrict output current to the secondary limit for the duration of the Kickstart period. After this time the Kickstart parts revert to their normal current limit. An example of Kickstart operation is in Figure 1.

Kickstart may be over-ridden by the thermal protection circuit and if sufficient internal heating occurs, Kickstart will be terminated and the output switch will be turned off. After the parts cools, if the load is still present $I_{OUT} \rightarrow I_{LIMIT}$, not I_{LIMIT_2nd} .

Figure 1. MIC2097 Kickstart Operation

Figure 1 Label Key:

- A. The MIC2097 is enabled into an excessive load (slew-rate limiting not visible at this time scale) The initial current surge is limited by either the overall circuit resistance and power-supply compliance, or the secondary current limit, whichever is less.
- B. R_{ON} of the power FET increases due to internal heating.
- C. Kickstart period.
- D. Current limiting initiated. FAULT/ goes low.
- E. V_{OUT} is non-zero (load is heavy, but not a dead short where $V_{OUT} = 0V$. Limiting response will be the same for dead shorts).
- F. Thermal shutdown followed by thermal cycling.
- G. Excessive load released, normal load remains. MIC2097 drops out of current limiting.
- H. FAULT/ delay period followed by FAULT/ going HIGH.

Enable Input

The ENABLE pin is a logic level compatible input which turns on or off the main MOSFET switch. There are two versions of each device. The -1 version has an active high (ENABLE) and the -2 version has an active low (ENABLE/).

Fault Output

The FAULT/ is an N-channel open-drain output, which is asserted (LOW true) when the device either begins current limiting or enters thermal shutdown. The FAULT/ signal asserts after a brief delay period in order to filter out very brief over current conditions. After an over-current or over-temperature fault clears, the FAULT/ pin remains asserted (low) for the delay period.

The FAULT/output is open-drain and must be pulled HIGH with an external resistor. The FAULT/ signal may be wire-OR'd with other similar outputs, sharing a single

pull-up resistor. FAULT/ may be tied to a pull-up voltage source which is less than or equal to V_{IN} .

Soft-Start Control

Large capacitive loads can create significant inrush current surges when charged through the current limiting switch. When the switch is enabled, the built-in soft-start limits the initial inrush current by slowly turning on the output.

Power Dissipation and Thermal Shutdown

Thermal shutdown is used to protect the current limiting switch from damage should the die temperature exceed a safe operating temperature. Thermal shutdown shuts off the output MOSFET and asserts the FAULT/ output if the die temperature reaches 145°C (typical).

The switch will automatically resume operation when the die temperature cools down to 135°C. If resumed operation results in reheating of the die, another shutdown cycle will occur and the switch will continue cycling between ON and OFF states until the reason for the overcurrent condition has been resolved.

Depending on PCB layout, package type, ambient temperature, etc., hundreds of milliseconds may elapse from the time a fault occurs to the time the output MOSFET will be shut off. This delay is caused because of the time it takes for the die to heat after the fault condition occurs.

Power dissipation depends on several factors such as the load, PCB layout, ambient temperature, and supply voltage. Calculation of power dissipation can be accomplished by the following equation:

$$P_D = R_{DS(ON)} \times (I_{OUT})^2 \quad \text{Eq. 2}$$

To relate this to junction temperature, the following equation can be used:

$$T_J = P_D \times R_{\theta(J-A)} + T_A \quad \text{Eq. 3}$$

Where T_J = junction temperature, T_A = ambient temperature, and $R_{\theta(J-A)}$ is the thermal resistance of the package.

In normal operation, excessive switch heating is most often caused by an output short circuit. If the output is shorted, when the switch is enabled, the switch limits the output current to the maximum value. The heat generated by the power dissipation of the switch continuously limiting the current may exceed the package and PCB's ability to cool the device and the switch will shut down and signal a fault condition. Please see the Fault Output description in the previous page for more details on the FAULT/ output. After the switch

shuts down, and cools, it will re-start itself if the Enable signal retains true (high on the ENABLE parts, low on the ENABLE/ parts).

In Figure 2, die temperature is plotted against I_{OUT} assuming a constant ambient temperature of 85°C. The plot also assumes the maximum specified switch resistance at high temperature.

Figure 2. Die Temperature vs. I_{OUT}

Setting I_{LIMIT}

The current limit of the MIC2097 and MIC2099 parts are user programmable and controlled by a resistor connected between the I_{LIMIT} pin and Ground. The value of the current limit resistor is determined by the following equations:

$$I_{LIMIT} = \frac{\text{CurrentLimitFactor}(\text{CLF})}{R_{LIMIT}} \quad \text{Eq. 4}$$

or

$$R_{LIMIT} = \frac{\text{CurrentLimitFactor}(\text{CLF})}{I_{LIMIT}} \quad \text{Eq. 5}$$

The Current-Limit Factor (CLF) is a number that is characteristic to the MIC2097/9 switches. The CLF is a product of the current-setting resistor value, and the desired current-limit value. Please note that the CLF varies with the current output current, so caution is necessary to use the correct CLF value for the current that you intend to use the part at. For example: If one wishes to set a $I_{LIMIT} = 1.1\text{A}$, looking in the electrical specifications we will find CLF at $I_{LIMIT} = 1.1\text{A}$, as noted in Table 1.

Min.	Typ.	Max.	Units
175	215	263	V

Table 1. CLF at $I_{LIMIT} = 1.1\text{A}$

For the sake of this example, the typical value of CLF at an I_{OUT} of 1.1A is 215V. Applying Equation 5:

$$R_{LIMIT}(\Omega) = \frac{215\text{V}}{1.1\text{A}} = 195\Omega \quad \text{Eq. 6}$$

Choose $R_{LIMIT} = 196\Omega$ (the closest standard 1% value)

Designers should be aware that variations in the measured I_{LIMIT} for a given R_{LIMIT} resistor, will occur because of small differences between individual ICs (inherent in silicon processing) resulting in a spread of I_{LIMIT} values. In the example above we used the typical value of CLF to calculate R_{LIMIT} . We can determine I_{LIMIT} 's spread by using the minimum and maximum values of CLF and the calculated value of R_{LIMIT} :

$$I_{LIMIT_MIN} = \frac{175\text{V}}{196\Omega} = 0.89\text{A} \quad \text{Eq. 7}$$

$$I_{LIMIT_MAX} = \frac{263\text{V}}{196\Omega} = 1.34\text{A} \quad \text{Eq. 8}$$

Giving us a maximum I_{LIMIT} variation of:

I_{LIMIT_MIN}	I_{LIMIT_TYP}	I_{LIMIT_MAX}
0.89A (-19%)	1.1A	1.34A (+22%)

For convenience, Table 2 lists the resistance values for the R_{SET} pin, for various current limit values.

Table 2. MIC2097 and MIC2099 R_{LIMIT} Table

I_{LIMIT} vs. I_{OUT} Measured

When in current limit, the switches are designed to act as a constant-current source to the load. As the load tries to pull more than the maximum current, V_{OUT} drops and the input-to-output voltage differential increases. As the $(V_{IN} - V_{OUT})$ voltage differential increases, the IC internal temperature also increases. To limit the IC's power dissipation, the current limit is reduced as a function of output voltage.

This folding back of I_{LIMIT} can be generalized by plotting I_{LIMIT} as a function of V_{OUT} , as shown in Figures 3 and 4. The slope of V_{OUT} between $I_{OUT} = 0V$ and $I_{OUT} = I_{LIMIT}$ (where I_{LIMIT} is a normalized 1A) is determined by R_{ON} of the switch and I_{LIMIT} .

Figure 3. Normalized Output Current vs. Output Voltage

Figure 4. Normalized Output Current vs. Output Voltage

When measuring I_{OUT} it is important to remember voltage dependence, otherwise the measurement data may appear to indicate a problem when none really exists. This voltage dependence is illustrated in Figures 5 and 6.

In Figure 5, output current is measured as V_{OUT} is pulled below V_{IN} , with the test terminating when V_{OUT} is 1V below V_{IN} . Observe that once I_{LIMIT} is reached I_{OUT} remains constant throughout the remainder of the test. In Figure 6 this test is repeated but with $(V_{IN} - V_{OUT})$ is 4V.

Figure 5. I_{OUT} in Current Limiting for $V_{OUT} = 4V$

Figure 6. I_{OUT} in Current Limiting for $V_{OUT} = 1V$

Under Voltage Lock Out (UVLO)

The switches have an Under Voltage Lock Out (UVLO) feature that will shut down the switch in a reproducible manner when the input power supply voltage goes too low. The UVLO circuit disables the output until the supply voltage exceeds the UVLO threshold. Hysteresis in the UVLO circuit prevents noise and finite circuit impedance from causing chatter during turn-on and turn-off. While disabled by the UVLO circuit, the output switch (power MOSFET) is OFF and no circuit functions, such as FAULT/ or ENABLE, are considered to be valid or operative.

Note: MIC2097-1; R5=NF; EN pin uses R4 (pull-up resistor to V_{IN}) to enable the output without an external enable signal. MIC2097-2; R4=NF; EN/ pin uses R5 (pull-down resistor to GND) to enable the output without an external enable signal.

Figure 9. MIC2099-1 Schematic

Note: MIC2099-1; R5=NF; EN pin uses R4 (pull-up resistor to V_{IN}) to enable the output without an external enable signal. MIC2099-2; R4=NF; EN/ pin uses R5 (pull-down resistor to GND) to enable the output without an external enable signal.

Evaluation Board Schematic

Figure 10. Schematic of MIC209X Evaluation Board

Notes:

1. Evaluation board is used for all parts.
2. Part numbering scheme is 209X-Y where X is the place holder for the last number (i.e. MIC2095, MIC2097, MIC2098 or MIC2099) and Y is the polarity of the enable signal (-1 indicates active high logic and -2 indicates active low logic).
3. MIC209X-1 EN pin only requires R4 (pull-up resistor to V_{IN}) to enable the output without an external enable signal.
4. MIC209X-2 EN/ pin only requires R3 (pull-down resistor-to-GND) to enable the output without an external enable signal.
5. R1 is NF (no fill) with the MIC2095 (fixed current limit).

NOTE:

1. ALL DIMENSIONS ARE IN MILLIMETERS.
2. MAX. PACKAGE WARPAGE IS 0.05 mm.
3. MAXIMUM ALLOWABLE BURRS IS 0.076 mm IN ALL DIRECTIONS.
4. PIN #1 ID ON TOP WILL BE LASER/INK MARKED.
5. DIMENSION APPLIES TO METALIZED TERMINAL AND IS MEASURED BETWEEN 0.20 AND 0.25 mm FROM TERMINAL TIP.
6. APPLIED ONLY FOR TERMINALS.
7. APPLIED FOR EXPOSED PAD AND TERMINALS.

6-Pin 1.6mm x 1.6mm TMLF (MT)

Recommended Landing Pattern

Recommended Land Pattern for MLF 1.6x1.6 6 Lead

LP # MLF1616D-6LD-LP-1

All units are in mm

Tolerance ± 0.05 if not noted

Red circle indicates Thermal Via. Size should be .300-.350 mm in diameter and it should be connected to GND plane for maximum thermal performance.
